Effect of Attic Type (Unvented vs Hybrid)

AUSTIN

2.5 % Difference
Background

- Ducts in vented attics are penalized by the cold winters and hot summers
  - The energy codes are pushing the idea to bring the ducts into conditioned space
  - Burying the ducts inside the attic insulation in the ceiling would effectively increase the R-value of the duct towards the attic
- The blown-in insulation in the attic is vapor permeable which may cause a condensation risk
  - The condensation risk has been largely not well-known despite of previous studies
Literature on buried ducts previously states encapsulation in moist/humid climates

**DOE Zero Energy exception to ducts in conditioned space (Apr ’14)**

In moist and marine climates minimum of R-8 duct insulation with min. 1.5” of closed-cell spray foam encapsulating the ducts

**U.S. Dept. of Energy Building America Measure Guideline (Aug ’13)**

Determine if ducts can be strictly buried in humid climates without condensation concerns

---

**DOE Zero Energy Ready Home National Program Requirements (Rev. 04) April 21, 2014.**

## Previous Work (Building America-Steven Winters)

**Duct configuration**

- Deeply-buried
- Fully-buried
- Partially-buried
- Truss lower chords
The monitored data from the South Carolina test house indicates that R-8 duct insulation appears to be sufficient to prevent condensation.

Regarding energy loss, the leakage rate of 1-2 CFM/100SFcf for the attic ducts was selected as a reasonable and achievable target.

The buried ducts delivered colder air during cooling than the attic ducts that were not buried (on average nearly 7°F colder). The lower delivery temperature results in increased energy savings and improved occupant comfort.

Simulations predicted 21% annual heating/cooling site energy savings compared to conventional insulated attic ducts. The compact duct component contributed approximately 13% of this energy savings, and the buried duct component contributed approximately 8%.

Develop design criteria for buried ducts that use common materials and do not rely on encapsulation using spray foam or disrupt traditional work sequences.
Is Encapsulation Needed?

- Previous studies by others resulted in a requirement to seal the ducts with 1.5” of closed cell spray foam insulation in addition to the existing duct insulation

- Consider that existing homes already have short “buried” duct section where the duct connects to the duct boot to supply air through ceiling
  - No condensation issues

- The existing requirements for buried ducts have likely been overly cautious
Approach (Three Prong Approach)

- **Hygrothermal modeling** of buried ducts exposed to constant and varying climatic conditions (**DYNAMICS**)
- Small-scale **laboratory** study
- **Field** testing

### Modeling
- **Thermal and moisture analysis for condensation**
  - Relative humidity
  - Vapor pressure
  - Temperature
  - Dew point
  - Square vs round ducts
  - OH climate (5A)
  - SC climate (3A)

### Lab-Scale
- **Lab-scale buried duct mimic evaluating %RH and condensation**
  - Duct type
  - Duct R-value
  - Loosefill R-value
  - “Attic” temperature and % RH
  - Duct temperature

### Field Evaluation
- **Monitoring residential buried duct installations for condensation**
  - OC – monitoring buried ducts in Cleveland, OH model home
  - Plus: HIRL – monitoring compact buried ducts in Lady’s Island, SC.
Simulation Results
Buried Ducts in Hot and Humid Attic

2-D Hygrothermal Model

- Attic = 130°F, 30%RH (90°F dew point)
- Duct = 55°F
- Held constant for 1 week.

- Round and square have different effective R-values vs Nominal R-value
- Location where duct may condense is typically mid-depth of blown insulation or above duct where vapor drive is coming from.

4” R-8 round duct

4” R-8 square duct, deeply buried

4” R-8 square duct

8” R-8 square duct, deeply buried
Simulations in Climatic Conditions

Full year simulation for Charleston, SC

- Constant duct temp. (45F, 50F, 55F)
- On-Off schedule (55F on-time)

- Mid-summer is not necessarily the most severe time of the year for condensation.
- Early fall may be most severe time.
Simulations in Climatic Conditions

Full year simulation for Cleveland, OH

- Simulated attic conditions
- Constant duct temp. (55°F)
- R38 and R49 loosefill level

- End of August is when highest %RH occurs on top of the duct.
Duct Buried in Insulation

Duct Condensation Analysis – Charleston SC
R8 vs R12 (6” square duct)

• 12” Loose Fill
• R8 all around vs. R8 bottom + R12 on sides and top

• Attic conditions

• Indoor conditions

  - No condensation with R12
Laboratory Testing
Laboratory testing for condensation

- **a**: Example of condensation in a laboratory setup.
- **b**: Close-up of a condensation event.
- **c**: Another angle or setup of the condensation test.
- **d**: Close-up of a condensation material.
- **e**: Setup or equipment used in the condensation test.
- **f**: Additional equipment or setup for the condensation test.

Flowchart:
- **dry** → **water contact** → **irreversible**

Laboratory testing results

Example buried duct experiment – Extreme S. Carolina conditions

- **Ducts**: R-8 flex, R-8.7 duct board
- **Attic insulation**: R-38 (no mounding)
- **Run time**: 22 days (100% cooling air on)

- Measured %RH around flex and board
- Black line = %RH within “indoor” space
- 8” and 10” flex sensors maintained max humidity for duration of test

<table>

- 8” above ceiling
- 10” above ceiling

*represents enclosed %RH*
Laboratory testing results

- **Flex duct:** visible moisture on surface, loosefill moist in vicinity, but not in all areas. Some indicator pieces unchanged while others turned red.
  - No dripping onto drywall prior to moving ducts during observation.

- **Duct board:** no visible moisture in areas of sensors, did not feel wet. No change in indicator tape near sensors. Moisture along top and edge at elbow. Tape changed to red in top middle.
  - No dripping onto drywall prior to moving ducts during observation.
Field Testing

Cleveland OH
Buried duct field testing (Cleveland, OH)

- A model home in Cleveland, OH with buried ducts that was outfitted with sensors for evaluation

Field Evaluation – Data Collection

Temp / %RH Sensors

- Flex Duct
  - 0”, 3 ½”, 7”, 9” (distance up from bottom of duct)
- Loosefill
  - 0”, 3 ½”, 7”, 9” (distance up from drywall)
- Duct Air (flex duct core)
- Attic Ambient (attic air space)
- Indoor (upstairs bedroom)
- Outdoor (outside deck)

- T/RH sensors installed around R8 flex duct
- T/RH sensors installed through loosefill
- R49 loosefill installed in the attic
Buried duct field testing (Cleveland, OH)

Data collection Feb 2016-Mar 2016

During cooling season, %RH increases
- Elevated humidity (≥ 90%) observed during limited days May – September.
- Measured periods of elevated humidity followed by low humidity.

During heating season, %RH around flex duct remains low.

<table>

Condensation Indicators

- No sign of condensation around the flex ducts
Summary

• Attics experience very dynamic conditions
  • Steady-state analyses can be misleading and result in overly conservative designs
  
• The laboratory and field tests as well as numerical simulations indicate that R-8 duct insulation could be sufficient to avoid condensation problems in deep buried ducts in moist climates

• Simulations and field tests did not show moisture accumulation that would have resulted in dripping water or wet insulation
Conclusions

• Currently the majority of residential homes that have ducts in vented attics have buried ducts
  • The hanging ducts that connect to the duct boots through the insulation layer have been working fine
• The results from the work suggest that R-8 buried duct system performs well in Climate Zone 5A
• Cost effective new options to drive energy saving
• Based on multiple studies, new building codes (ICC 2018) will include:
Buried Duct Code Proposal

**R403.3 Ducts**

**R403.3.6 Ducts buried within ceiling insulation**

1. Supply and return ducts insulated with \( \geq R-8 \)
2. Sum of ceiling insulation R-values above and below duct \( \geq R-19 \) (excluding duct R-value)

3. CZ 1A, 2A, 3A where supply ducts are completely covered with ceiling insulation should be insulated with \( \geq R-13 \) and vapor retarder

**R403.3.6.1 Deeply buried effective R-value**

1. Installed according to R403.3.6
2. On or within 5.5” of ceiling board and surrounded with \( \geq R-30 \) attic insulation and top of the duct is minimum 3.5” below insulation

3. Claim effective R-value of R-25 for deeply buried section

**R403.3.7 Ducts located in conditioned space**

1. Duct system located completely within continuous air barrier and building thermal envelope
2. Installed according to R403.3.6
3. Air handler within continuous air barrier and building thermal envelope

4. Duct leakage (rough-in ducts or post-construction total system to outside) \( \leq 1.5 \text{CFM/100SF CFA} \)

5. Ceiling insulation immediately above insulated duct \( \geq \) proposed ceiling R-value minus insulated duct R-value
